What Is Photocontact Dermatitis?Who Gets Photocontact Dermatitis?What Causes Photocontact Dermatitis?What Causes Phototoxic Contact Dermatitis?What Causes Photoallergic Contact Dermatitis?What Are The Clinical Features of Photocontact Dermatitis?Clinical Features of Phototoxic Contact DermatitisClinical Features of Photoallergic Contact DermatitisWhat Are The Complications of Photocontact Dermatitis?How Is Photocontact Dermatitis Diagnosed?PACD is an immunological reaction -- specifically, a delayed-type hypersensitivity reaction that occurs against a light-activated photosensitising agent. When this agent is applied to the skin and then exposed to UV rays, in some individuals a small portion of the substance (hapten) binds to a protein in the skin to form an antigen. This antigen is ...See more on dermnetz Published: Oct 26, 2023.

Photocontact Dermatitis

Photocontact dermatitis (PCD) is a type of allergic reaction that occurs when a person's skin comes into contact with a substance that causes an allergic reaction. This reaction is triggered by light, specifically ultraviolet (UV) radiation. The reaction is typically delayed, meaning it does not occur immediately after contact with the allergen. Instead, it usually develops within 24 to 72 hours. The symptoms of PCD can range from mild redness and itching to severe blistering and swelling. The most common sites of PCD are the face, neck, and hands. However, it can also affect other parts of the body, including the arms and legs. The reaction is most common in people who work in agriculture, construction, or other outdoor occupations. It is also common in people who use certain medications, such as antibiotics and diuretics. The reaction is most common in people who have a history of allergic reactions. The reaction is most common in people who have a history of allergic reactions. The reaction is most common in people who have a history of allergic reactions.
